

New Physics in the Flavour Sector

ANDREAS CRIVELLIN

Paul Scherrer Institut, CH-5232 Villigen PSI, Switzerland

Several experiments observed deviations from the Standard Model (SM) in the flavour sector: LHCb found a $4 - 5\sigma$ discrepancy compared to the SM in $b \rightarrow s\mu^+\mu^-$ transitions (recently supported by an Belle analysis) and CMS reported a non-zero measurement of $h \rightarrow \mu\tau$ with a significance of 2.4σ . Furthermore, BELLE, BABAR and LHCb founds hints for the violation of flavour universality in $B \rightarrow D^{(*)}\tau\nu$. In addition, there is the long-standing discrepancy in the anomalous magnetic moment of the muon. Interestingly, all these anomalies are related to muons and taus, while the corresponding electron channels seem to be SM like. This suggests that these deviations from the SM might be correlated and we briefly review some selected models providing simultaneous explanations.

1 Introduction

The discovery the Higgs at the LHC provided the final ingredient of the SM. While no direct evidence for physics beyond the SM was found during the first LHC run, there are some interesting indirect hints for NP in the flavor sector, mainly in semileptonic decays of B -mesons, the SM-forbidden decay $h \rightarrow \mu\tau$ of the Higgs boson and the long-lasting discrepancy in the anomalous magnetic moment (AMM) of the muon^a.

$b \rightarrow s\ell^+\ell^-$: Deviations from the SM found by LHCb⁴ in the decay $B \rightarrow K^*\mu^+\mu^-$ arise mainly in an angular observable called $P_5^{\prime 5}$, with a significance of $2-3\sigma$ depending on assumptions made for the hadronic uncertainties^{6,7,8}. This measurement recently received support from a (less precise) BELLE measurement⁹. In the decay $B_s \rightarrow \phi\mu^+\mu^-$, LHCb also uncovered¹⁰ deviations compared to the SM prediction from lattice QCD^{11,12} of 3.5σ significance⁷. LHCb has further observed lepton flavor universality violation (LFUV) in $B \rightarrow K\ell^+\ell^-$ decays¹³ across the dilepton invariant-mass-squared range $1\text{ GeV}^2 < m_{\ell\ell}^2 < 6\text{ GeV}^2$. Here, the measured ratio branching fraction ratio $R(K) = \frac{\text{Br}[B \rightarrow K\mu^+\mu^-]}{\text{Br}[B \rightarrow Ke^+e^-]}$ disagrees with the theoretically clean SM prediction by 2.6σ . Combining these observables with other $b \rightarrow s$ transitions, it is found that NP is preferred over the SM by $4-5\sigma$ ^{14,15,16}.

$B \rightarrow D^{(*)}\tau\nu_\tau$: Hints for LFUV in these modes were observed first by the BaBar collaboration¹⁷ in 2012. These measurements have been confirmed by BELLE^{18,19} and LHCb has

^aWe do not discuss the anomaly in e'/e ¹ here for which possible solutions include Z' bosons² or the MSSM³.

remeasured $B \rightarrow D^* \tau \nu_\tau$ ²⁰. For the ratio $R(X) \equiv \text{Br}[B \rightarrow X \tau \nu_\tau] / \text{Br}[B \rightarrow X \ell \nu_\ell]$, the current HFAG average²¹ of these measurements is $R(D)_{\text{exp}} = 0.397 \pm 0.040 \pm 0.028$, $R(D^*)_{\text{exp}} = 0.316 \pm 0.016 \pm 0.010$. Comparing these results to the SM predictions²² $R_{\text{SM}}(D) = 0.297 \pm 0.017$ and $R_{\text{SM}}(D^*) = 0.252 \pm 0.003$, there is a combined discrepancy of 4.0σ ²¹.

$h \rightarrow \mu\tau$: In the Higgs sector, CMS has presented results for a search for the lepton-flavor-violating (LFV) decay mode $h \rightarrow \mu\tau$, with a preferred value²³ $\text{Br}[h \rightarrow \mu\tau] = (0.84^{+0.39}_{-0.37})\%$. This is consistent with the less precise ATLAS measurement²⁴, giving a combined significance for NP of 2.6σ , since such a decay is forbidden in the SM. This decay mode is of considerable interest because it hints at LFV in the charged-lepton sector, whereas up to now, LFV has only been observed in the neutrino sector via oscillations.

a_μ : The AMM of the muon $a_\mu \equiv (g-2)_\mu/2$, provides another motivation for NP connected to muons. The experimental value of a_μ is completely dominated by the Brookhaven experiment E821²⁵ and is given by $a_\mu^{\text{exp}} = (116\,592\,091 \pm 54 \pm 33) \times 10^{-11}$, where the first error is statistical and the second systematic. The SM prediction is²⁶ $a_\mu^{\text{SM}} = (116\,591\,855 \pm 59) \times 10^{-11}$, where almost the entire uncertainty is due to hadronic effects. This amounts to a discrepancy between the SM and experimental values of $\Delta a_\mu = a_\mu^{\text{exp}} - a_\mu^{\text{SM}} = (236 \pm 87) \times 10^{-11}$, i.e. a 2.7σ deviation^b.

2 Explanations

$b \rightarrow s\ell^+\ell^-$: Here a flavour changing neutral current is required which can be naturally generated at tree-level by a Z' vector bosons^{27,28,29,30,31,32,33,34,35,36} or by leptoquarks^{37,38,39,40,41,42}.

$B \rightarrow D^{(*)}\tau\nu_\tau$: Here a tree-level NP contribution is required in order to generate the desired effect of the order of 25% compared to the SM. Charged Higgses^{43,44,45,46,47} are one possibility, leading to large effects in the q^2 distribution. In addition, leptoquarks provide a valid explanation^{48,49,50,40,41,51,52,42} but also charged vector bosons are possible⁵³.

a_μ : NP in $b \rightarrow s\mu^+\mu^-$ should also contribute to the AMM of the muon. Explanations besides supersymmetry (see for example Ref.⁵⁴ for a review) include leptoquarks^{55,56}, new scalar contributions in two-Higgs-doublet models (2HDM)^{57,47}, and very light Z' bosons^{58,59}.

$h \rightarrow \mu\tau$: Since the B physics anomalies are related to τ and μ leptons, a connection to $h \rightarrow \mu\tau$ seems plausible. As the central value for the $h \rightarrow \mu\tau$ branching ratio is large, loop effects are in general not sufficient to generate the desired effect⁶⁰. Furthermore, also adding only vector-like fermions is not sufficient as the bounds from $\tau \rightarrow 3\mu$ and $\tau \rightarrow \mu\gamma$ are too stringent⁶¹. Therefore, introducing additional scalars is the most popular option (see for example^{62,63,31,60}).

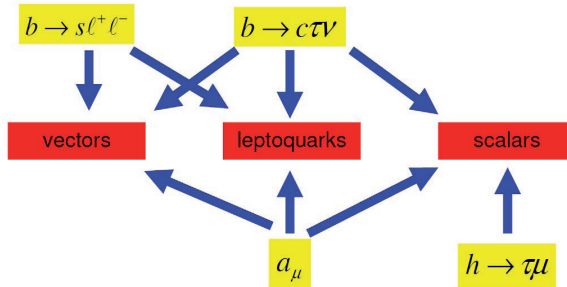

Figure 1 – Schematic picture of the implications for new particles from the various anomalies.

^bLess conservative estimates even lead to discrepancies up to 3.6σ in a_μ

3 Selected models for simultaneous explanations of anomalies

Multi Higgs $L_\mu - L_\tau$ model: $h \rightarrow \tau\mu$ and $b \rightarrow s\mu^+\mu^-$ ^{31,32}

Adding to a gauged $L_\mu - L_\tau$ model with vector like quarks ³⁰ a second Higgs doublet with $L_\mu - L_\tau$ charge 2 can naturally give an effect in $h \rightarrow \tau\mu$ via a mixing among the neutral CP-even components of the scalar doublets. In this setup a Z' boson, which can explain the $b \rightarrow s\mu^+\mu^-$ anomalies, gives sizable effects in $\tau \rightarrow 3\mu$ which are potentially observable at LHCb and especially at BELLE II. One can avoid the introduction of vector-like quarks by assigning horizontal charges to quarks as well ³². Then, the effects in $b \rightarrow s$, $b \rightarrow d$ and $s \rightarrow d$ transitions are related in an MFV-like way by CKM elements and the Z' can have an observable cross section at the LHC.

Leptoquarks: $b \rightarrow s\mu^+\mu^-$ and $b \rightarrow c\tau\nu$ ⁴¹

While in $b \rightarrow c\tau\nu$ both leptoquarks and the SM contribute at tree-level, in $b \rightarrow s\mu^+\mu^-$ one compares a potential tree-level NP contribution to a loop effect^c. However, as $b \rightarrow c\tau\nu$ involves three times the third generation (assuming that the neutrino is of tau flavour in order to get interference with the SM contribution) but $b \rightarrow s\mu^+\mu^-$ only once. Therefore, leptoquarks with hierarchical flavour structure, i.e. predominantly coupling to the third generation ^{64,65}, can explain simultaneously $b \rightarrow s\mu^+\mu^-$ and $b \rightarrow c\tau\nu$ in case of a $C_9 = -C_{10}$ (left-handed quark and lepton current) solution for $b \rightarrow s\mu^+\mu^-$. In this case one predicts sizable effects in $B \rightarrow K^{(*)}\tau\tau$, $B_s \rightarrow \tau^+\tau^-$ and $B_s \rightarrow \mu^+\mu^-$ below the SM, while the effects in $b \rightarrow s\tau\mu$ are at most of the order of 10^{-5} .

2HDM X: a_μ and $b \rightarrow c\tau\nu$ ⁴⁷

In a 2HDM of type X, the couplings of the additional Higgses to charged leptons are enhanced by $\tan\beta$. As, unlike for the 2HDM II, this enhancement is not present for quarks, the direct LHC bounds on $H^0, A^0 \rightarrow \tau^+\tau^-$ are not very stringent and also $b \rightarrow s\gamma$ poses quite weak constraints. Therefore, the additional Higgses can be light which, together with the $\tan\beta$ enhanced couplings to muons, allows for an explanation of a_μ . If one adds couplings of the lepton-Higgs-doublet to third generation quarks, one can explain $b \rightarrow c\tau\nu$ as well by a charged Higgs exchange. In case of a simultaneous explanation of a_μ and $b \rightarrow c\tau\nu$ (without violating bounds from $\tau \rightarrow \mu\nu\nu$) within this model, sizable branching ratios (reaching even the % level) for $t \rightarrow Hc$, with $m_H \approx 50 - 100$ GeV and decaying mainly to $\tau\tau$, are predicted. Again, such a signature could be observed at the LHC.

$L_\mu - L_\tau$ flavon model: a_μ , $h \rightarrow \tau\mu$ and $b \rightarrow s\mu^+\mu^-$ ⁶⁶

In this model one adds vector-like leptons to the gauged $L_\mu - L_\tau$ model of Ref. ³⁰ and one can explain $h \rightarrow \tau\mu$ via a mixing of the flavon (the scalar which breaks $L_\mu - L_\tau$) with the SM Higgs. Furthermore, one can account for a_μ by loops involving the flavon and vector-like leptons without violating the $\tau \rightarrow \mu\gamma$ bounds as this decay is protected by the $L_\mu - L_\tau$ symmetry. Despite the effects already present in the model of Ref. ³¹, one expects order one effects in $h \rightarrow \mu^+\mu^-$ detectable with the high luminosity LHC.

4 Conclusions

In these proceedings we reviewed the anomalies in the flavour sector related to charged leptons together with some of their possible explanations. Interestingly, all anomalies involve muons and/or taus while the corresponding electron channels seem to agree with the SM predictions. This coherent picture of lepton flavour (universality) violation^d agrees with the stringent LEP constraints and suggests that the anomalies could be related, hinting at an unified explanation within a NP model. In Fig. 1 we show in a schematic way which relations among the anomalies and new particles arise. Specific NP models can of course include the addition several new

^cAlternatively, there is one leptoquark representation for which one can explain $b \rightarrow s\mu^+\mu^-$ by a loop effect and $b \rightarrow c\tau\nu$ at tree-level in the case on anarchic couplings⁵¹ and even explain the AMM of the muon.

^dFor the implications in Kaon decays see ⁶⁷.

particles, potentially explain all anomalies and predict correlations among them and with other observables or processes detectable in future experiments.
